## Introduction, Motivation and the Language

General Comments.

### 1.1 Overview of the course. Administrative, Academic policies

## 1.2 Introduction and Motivation

Main theme of this course is to use algebra to solve computational problems. Let us consider the following two problems :

**Plagiarism check** Given two  $C$  programs  $P_1$  and  $P_2$  check if they are the same under renaming of variables

**Molecule detection** Given two chemical molecules check if they have the same structure.

Note that both these problems can be modelled using a graph. For example, in the second case one could view the molecule being given as adjacency matrix. Our aim in both cases are similar which is to check if there is isomorphism between two graphs.

**DEFINITION 1.1 (Graph Isomorphism).** Two graphs  $X_1(V_1, E_1)$ ,  $X_2(V_2, E_2)$  are said to be isomorphic if there is a bijective map  $\sigma : V_1 \rightarrow V_2$  such that  $\forall (u, v) \in V_1 \times V_1$ ,

$$(u, v) \in E_1 \iff (\sigma(u), \sigma(v)) \in E_2$$

**PROBLEM 1.2.** The *graph isomorphism problem* is the decision problem of checking if given two graphs  $X_1, X_2$  are isomorphic.

We are also interested in the following special case of the above problem called graph automorphism problem.

**DEFINITION 1.3 (Graph Automorphism).** For a graph  $X(V, E)$ , an automorphism of  $X$  is a renaming of the vertices of  $X$  given by a bijective map  $\sigma : V \rightarrow V$  such that  $\forall (u, v) \in V \times V$ ,

$$(u, v) \in E \iff (\sigma(u), \sigma(v)) \in E$$

We are interested in the set of all bijections such that they are automorphisms of  $X$ . We denote this by  $Aut(X)$ .

**DEFINITION 1.4.** For a graph  $X$  on  $n$  vertices,  $Aut(X) = \{\sigma \mid \sigma : [n] \rightarrow [n], \sigma \text{ is an automorphism of } X\}$

Note that an identity map which takes a vertex to itself always belongs to  $Aut(X)$  for all graphs  $X$ . Hence the question is are there any bijections other than the identity map as automorphism of  $X$ .

**PROBLEM 1.5 (Graph Automorphism Problem).** Given a graph  $X$  does  $Aut(X)$  has any element other than the identity element.

One way to see bijections is via permutations. Let  $X$  be an  $n$  vertex graph. Denote  $S_n$  to be the set of all permutations on  $n$  elements. Hence  $Aut(X)$  can be defined as  $\{\sigma \mid \sigma \in S_n \text{ and } \sigma \text{ is an automorphism of } X\}$ .

## LECTURE

# 8

### Proof of Buchberger's criterion.

Preamble

#### 8.1 A Structure Lemma

#### 8.2 A Proof by Contradiction

## Minimality, Elimination Theory

### Preamble

Minimal and Reduced Grobner Basis. Ideal Equality Problem. Uniqueness of Reduced Grobner basis. Elimination Theory and Elimination Ideals. Grobner Basis for the Elimination Ideals. Relating to the Robotics Arms problem.

### 9.1 Minimal and Reduced Grobner Basis

### 9.2 Uniqueness of Reduced Grobner basis

### 9.3 Elimination Theory and Elimination Ideals

### 9.4 Grobner Basis for the Elimination Ideals

## An application of Monomial ordering

### Preamble

Applications of Grobner Basis. 3-coloring via Grobner basis. Testing membership in Kernel and Image of Ring Homomorphisms. Applications to Integer Programming.

### 10.1 Applications of Grobner Basis

#### 10.1.1 3-coloring via Grobner Basis

### 10.2 Integer Programming

#### 10.2.1 Formulation as polynomials

#### 10.2.2 $\mathbb{F}$ -algebra homomorphism

#### 10.2.3 Kernel

#### 10.2.4 Testing membership in the image

#### 10.2.5 Bringing in optimisation

## Integer Programming using Grobner Basis

Proof of the characterization of the Image of the  $k$ -algebra homomorphism. Observation about the Grobner basis in the special case of integer programming. Defining the monomial ordering to bring in optimization. Proof of optimality of the solution.

### 11.1 Characterizing the Image

### 11.2 Observations on the Grobner Basis

### 11.3 Bringing in Optimality

### 11.4 Remarks about generalizations

## From Root Finding to Factorization

*Shorter Lecture:* From Root finding to factorization of polynomials. Why or when is a polynomial completely factorizable over the underlying ring/field? Why should they be unique factorizable? Informal answers, and directions to explore.

### 12.1 Number of Roots

### 12.2 A Linear Algebraic Method - The companion Matrix

### 12.3 From Roots to Factorization

### 12.4 Informal Answers and the road ahead

## Unique Factorization Domains

Irreducible and Prime Elements in an Integral Domain. Primes are irreducible. When is it that all irreducibles are primes? A proof that this is exactly when the domain is a UFD. A field is a UFD. Every principal Ideal Domain (example:  $F[x]$  and  $\mathbb{Z}$ ) is a UFD. What about rings like  $F[x_1, x_2]$ , and  $\mathbb{Z}[x]$ ? Gauss's theorem : If  $R$  is a UFD, then so is  $R[x]$ . Proof of the theorem using the characterization about irreducibles in  $R[x]$ . The case when the irreducibles are from  $R$  itself (Gauss's Lemma).

### 13.1 Irreducible vs Prime Elements of an Integral Domain

### 13.2 A characterization of Unique Factorizability

### 13.3 A Non-trivial Application - All Principal Ideal Domains are Unique Factorization Domains

### 13.4 Gauss's Theorem

#### 13.4.1 All constant primes in $R$ are primes in $R[x]$

#### 13.4.2 All non-constant irreducibles in $\mathbb{Z}[x]$ are irreducibles in $\mathbb{Q}[x]$

All primes in  $\mathbb{Q}[x]$  are primes in  $\mathbb{Z}[x]$

## Irreducibility

Continuing the proof of Gauss's theorem : The case when the irreducibles are from the  $\mathbb{R}[x]$ . Moving the argument to the Field of Fractions. Conclusion : Two tasks are well-framed.

- How do we detect irreducibility?
- How do we factorize into irreducible factors?

Eisenstein criterion for irreducibility.

### 14.1 Completing Gauss's Theorem

### 14.2 A Remark about Field of Fractions

### 14.3 Eisenstein criterion for irreducibility

## Quotient Rings and First Isomorphism Theorem

Quotient Rings. Irreducibility and Quotient Rings. First Isomorphism Theorem for the Quotient Ring. Application 1 : Chinese remaindering theorem. Application 2 : From Quotient Rings of Irreducible polynomials to Field extensions.

### 15.1 Quotient Rings and Irreducibility

### 15.2 Quotient Rings and First Isomorphism Theorem

### 15.3 Application 1 : Chinese Remaindering Theorem

### 15.4 Application 2 : From Irreducibility to Field Extensions

## More on Fields

Quick introduction to vector spaces. Viewing field extensions as vector spaces. Characteristic of a field. Sizes of fields. Constructing extensions and uniqueness of fields of a given size (up to isomorphism).

### 16.1 Field Extensions as Vector Spaces

A vector space over a field  $\mathbb{F}$  is a set  $V$  with two kinds of operations - addition and scalar multiplications - satisfying the following properties. Elements of  $V$  are called vectors and elements of  $\mathbb{F}$  are called scalars.

- $(V, +)$  forms an abelian group.
- If  $\alpha$  is a scalar, and  $v$  is a vector, then  $\alpha v$  is a vector.
- If  $\alpha$  is a scalar, and  $u$  and  $v$  are vectors, then  $\alpha(u + v)$  is the same vector as  $\alpha u + \alpha v$ .
- If  $\alpha_1, \alpha_2$  are scalars, and  $v$  is a vector, then  $\alpha_1(\alpha_2 v)$  is the same vector as  $(\alpha_1 \alpha_2)v$  where  $\alpha_1 \alpha_2$  is the multiplication in  $\mathbb{F}$ .

Some easy examples are the set of points in  $\mathbb{R} \times \mathbb{R}$ . Set of polynomials of degree  $d$  over a field  $\mathbb{F}$  forms a vector space with the natural notion of addition and multiplication.

Let  $E$  be a field and  $F$  be a subfield of it. One can view  $E$  as a vector space over  $F$ . To see this, view the elements of  $F$  as scalars and the elements of  $E$  as vectors in the above definition.

#### 16.1.1 Linear Independence, Basis, and Dimension

DEFINITION 16.1. A set of vectors  $v_1, v_2, \dots, v_k$  are said to be *linearly independent*, if:

$$\alpha_1 v_1 + \alpha_2 v_2 + \dots + \alpha_k v_k = 0 \implies \alpha_1 = 0 \wedge \alpha_2 = 0 \wedge \dots \wedge \alpha_k = 0$$

For any set  $S$  of vectors, the set of vectors spanned by it, denoted by  $\text{SPAN}(S)$  is the set of vectors that can be expressed as the linear combination of vectors in  $S$ . A set  $S$  is said to be a basis of a vector space, if  $S$  itself is linearly independent and the  $\text{SPAN}(S)$  is the whole space.

We need two observations about the basis of a vector spaces and basis.

All basis of a vector space are of the same size. Suppose there is an  $S$  and an  $S'$  which forms the basis of the same vector space  $V$ , and  $|S| > |S'|$ . Since  $S$  and  $S'$  are subsets of  $V$  itself, the elements of  $S'$  **Jayalal says: This needs to be completed.**

Since all basis of a vector space are of the same size - it must be the case that.

### 16.1.2 Minimal Polynomials - viewing adjoining as a vector space

## 16.2 Characteristic of Rings & Fields

Consider the following Ring homomorphism from  $\mathbb{Z}$  to a ring  $R$ .

$$\phi : \mathbb{Z} \rightarrow R$$

where,  $\forall a \in \mathbb{Z}$ ,  $\phi(a) = |a|.1$  if  $a > 0$ , and  $\phi(a) = |a|.(-1)$  if  $a < 0$ . where  $n.1$  is simply a notation for adding the identity of the ring  $R$ ,  $n$  times to itself.

We will first check that it is a ring homomorphism. **Jayalal says: Yet to be written**

Let  $I$  be the kernel of this map. Since  $\mathbb{Z}$  is a principal ideal domain,  $I$  is singly generated and the generator is simply the least number in absolute value. Let  $\ell$  be the generator of the ideal. We know that the ideal  $I$  is simply  $\ell\mathbb{Z}$ . This  $\ell$  is called the characteristic of the ring  $R$ . In other words, *characteristic of a ring  $R$  with identity is simply the smallest number of times one needs to add 1 to get to 0*. Indeed, it is possible that adding the identity to itself never gets to 0 of the ring. In this case  $I = 0$  and  $\ell = 0$  - we say that the characteristic of the ring is 0.

We explore more properties that can be derived from this  $\ell$ . Let  $R'$  be the image of this homomorphism. We know that  $R'$  is a subring of  $R$ . Consider the quotient ring  $\mathbb{Z}/\ell\mathbb{Z}$  which is same as  $\mathbb{Z}_\ell$ . By the first isomorphism theorem we have the following:  $\mathbb{Z}_\ell \cong R'$ . In other words, if the characteristic of a ring  $R$  is  $\ell$ , then there is an isomorphic copy of  $\mathbb{Z}_\ell$  sitting inside  $R$  as a subring.

Now we turn to characteristic of a field. First of all let us argue that it can only be zero or a prime number.

**LEMMA 16.2.** *The characteristic of a field is either a prime number or zero.*

*Proof.* Let  $F$  be a field. Suppose the characteristic is not a prime and is  $\ell \in \mathbb{Z}$ . Assume for the contradiction that  $\ell$  is not prime.  $\ell = p.q$  where  $p, q < n$ . Indeed,  $\ell$  is least integer such that  $\ell.n = 0$ . Hence  $p.1 \neq 0$  and  $q.1 \neq 0$ . Since  $\phi$  is a homomorphism, associated with the  $\ell$  that we discussed above,  $\phi(pq) = \phi(p)\phi(q)$ . Since the LHS is 0,  $\phi(p)$  and  $\phi(q)$  forms zero divisors in  $\mathbb{F}$ . Thus, we have arrived at a contradiction and hence the lemma.  $\square$

**COROLLARY 16.3.** *Any finite field must have a subfield whose order is a prime number.*

*Proof.* Let  $F$  be a finite field. We first argue that the characteristic cannot be zero. If it is zero, then we know that the ideal  $I$  in the above discussion is the zero ideal and hence the quotient ring is  $\mathbb{Z}$  itself. Hence,  $\exists R' \subseteq F$  such that  $\mathbb{Z} \cong R'$ , which implies that  $\mathbb{F}$  must have infinite cardinality. Thus, characteristic can only be a prime number. Thus, an isomorphic copy of  $\mathbb{Z}_p$  for some prime  $p$  must be present in every field.  $\square$

## 16.3 Sizes of Finite Fields

We combine the ideas developed in the previous two sections to conclude that the sizes of finite fields cannot be arbitrary.

**LEMMA 16.4.** *The size of any finite field is always of the form  $p^d$  for some prime  $p$  and a non-negative integer  $d$ .*

*Proof.*  $\mathbb{Z}_p$  (for some prime  $p$ ) appears a subfield (up to isomorphism) of any finite field. Let  $d$  be the dimension of  $F$  as a vector space over  $\mathbb{Z}_p$ . That is, there is a subset  $S \subseteq F$  with  $|S| = d$ , which forms the basis of  $F$  over  $\mathbb{Z}_p$ . Let us say that  $S = \{a_1, a_2, \dots, a_d\}$ . Indeed, each vector (each element of  $a \in \mathbb{F}$ ) can be viewed as a  $d$ -tuple  $(\alpha_1, \alpha_2, \dots, \alpha_d)$  such that  $a = \alpha_1 a_1 + \alpha_2 a_2 + \dots + \alpha_d a_d$ . Can two tuples represent the same  $a$ ? No, because it would mean then that  $\sum_i \alpha_i a_i = \sum_i \alpha' a_i$ . This contradicts the fact that  $S$  is linearly independent (since it forms a basis of  $\mathbb{F}$ ). Hence there are precisely  $p^d$  tuples possible, each of them representing distinct elements of  $\mathbb{F}$  as a vector space over  $\mathbb{Z}_p$ . Hence the size of the field  $\mathbb{F}$  must be exactly  $p^d$ .  $\square$

## 16.4 Constructing Field Extensions

For any  $p$  and  $d$ , is there a field of size  $p^d$ . We will answer this question positively.

Consider a polynomial  $p(x)$  of degree  $d$  that is irreducible over  $\mathbb{Z}_p$ . Let  $a$  be a root of such a polynomial. Clearly  $a \notin \mathbb{Z}_p$ . Consider the field  $\mathbb{Z}_p/\langle p \rangle$ . This is isomorphic to  $\mathbb{Z}_p(a)$  which also is a vector space over  $\mathbb{Z}_p$ .

We argue that the size of this finite field is precisely  $p^d$ . First of all, we argue that any element of the space  $\mathbb{Z}_p(a)$  can be viewed as a linear combination of elements in  $\{1, a, a^2, \dots, a^{d-1}\}$ . We do not need an  $a^d$  in this expression - indeed, it can be written as a combination of the other elements of lesser power since  $p(a) = 0$ . Suppose there is a linear combination of  $(1, a, a^2, \dots, a^{d-1})$  that goes to zero, that is  $a$  is a root of the polynomial of lesser degree than  $p(a)$ . But then there is a polynomial of degree less than  $p(x)$  which has  $a$  as the root.

## 16.5 Uniqueness of Fields up to isomorphism

We will be greedy, for any  $p$  and  $d$ , are there two non-isomorphic fields of size  $p^d$ ? We will answer this question negatively. So, we can always talk about *the* field of size  $p^d$ . **Jayalal says: Define splitting field etc.**

LEMMA 16.5. *The splitting field of a polynomial are always isomorphic to each other.*

*Proof.* **Jayalal says: Yet to be written**  $\square$

LEMMA 16.6. *For any field  $\mathbb{F}$ , there is a polynomial whose splitting field is  $\mathbb{F}$ .*

*Proof.* Let  $|\mathbb{F}| = k$ . Consider the multiplicative group  $\mathbb{F} - \{0\}$ . Let  $g$  be an element in this group. We know by Lagrange's theorem,  $g^{k-1} = 1$  where 1 is the multiplicative identity. Thus for all  $g \in \mathbb{F}$ ,  $g^k = g$ . Thus all of them are roots of the polynomial  $x^k - x$ , as a polynomial in  $\mathbb{F}[x]$ . Since this polynomial can have at most  $k$  roots, the polynomial completely splits in  $\mathbb{F}$  and it does not split in any subfield of  $\mathbb{F}$ . Hence  $\mathbb{F}$  is the splitting field of the polynomial  $x^k - x$ .  $\square$

By combining the above two lemmas, we get the main point of this section. That finite fields of a fixed size must be isomorphic.

## Warming up to Berlekamp's Factorization Algorithm

Back to Factorization problem. A starting idea to use Fermat's little theorem to extract product of linear factors. Reduction to Squarefree case. Frobenius map ( $x^q = x$ ) and the sub-algebra of the quotient ring  $F[x]/f$ . Dimension of the sub-algebra when  $f$  is irreducible.

## Berlekamp's Factorization Algorithm

Writing a set of linear equations and the Berlekamp Matrix. The  $O((qn^3)(n^2)(qn^2))$  time algorithm. Reducing the first factor of  $q$  by faster exponentiation. Removing the second factor of  $q$ . Identifying the minimal polynomial for the  $g(x)$ .

## Berlekamp's Factorization Algorithm

Computing the minimal polynomial of  $g(x)$ . Factorizing the minimal polynomial by Rabin's factorization method. Discussions on effect of choosing  $g(x)$  in  $\mathbb{W}$ , at random.

Berlekamp's Algorithm.

**20.1 The Berlekamp Subalgebra  $\mathbb{W}$**

**20.2 From Number of Irreducible Factors to Dimension**

**20.3 Using  $\mathbb{W}$  for factorization**

**20.4 Constructing a basis for  $\mathbb{W}$  - a linear algebraic approach**
